

Are you tired of the Rattle and Noise in your Cattle Crush?

Apply the “Rattle Test”

Many cattlemen I have known all have one thing in common, that is most of them are half deaf. How much of this is due to the noise of poorly designed and built cattle crushes.

A good test to apply before purchasing any new crush is the “Rattle Test”. In other words, stand beside the crush and shake it as hard as you can. This is the noise you are going to work with every time you process cattle. This noise is only going to get worse as the crush gets worn.

Also, how much of this noise adds stress and stirs cattle up? When an animal is caught in a head bail, fighting and pulling back, it creates more noise, more stress and tends to have a negative flow on effect to the following cattle.

Silencer comes with a unique patented Noise Reduction System (NRS) which means all contact points are sheathed in polyethylene with no steel on steel chatter of other crushes. This ensures a greatly reduced noise level during operation. Silencer has earned the reputation for promoting operator ease and safety and at the same time provides a quieter less stressful environment for livestock and staff. Livestock facility experts are talking “Noise Reduction System” for a good reason.
